

Injectable Lipolysis (Fat Removal Injection)

Injectable lipolysis, or a **fat removal injection**, is a method of fighting small to medium-sized body and face fat deposits without surgery.

Aqualyx is the only **injectable lipolysis** product approved for use throughout Europe and specifically in Switzerland, which has been proven to effectively reduce fat deposits.

When you inject Aqualyx, local fat deposits are ablated on the chin, hips, abdomen, thighs, buttocks, upper thighs and knees, which gives your curves an elegant appearance.

Deoxycholic acid, the active ingredient of **Aqualyx**, breaks down fat where it needs to be broken down. Fat breaks down into smaller molecules, so-called fatty acids, which are then, after about 3 weeks, excreted through lymphatic and blood channels and enter the metabolism. At the same time, most of these fatty acids can be used by the body as an energy supplier. Therefore, the accompanying nutrition correction coupled with physical exercises increases the success of any **Aqualyx** treatment. Otherwise, fat redistribution may occur.

Today, it is believed that fat cells destroyed in the course of therapeutic treatment are not formed again.

The number of sessions depends on the desired degree of correction, size of fat deposits and individual response of the adipose tissue. At least 3 to 5 treatment sessions at intervals of 3 or 4 weeks are needed to achieve the intended effect. Aqualyx treatment does not lead to any weight loss. A healthy diet and regular exercise are the key to successful treatment.
